#### AMORTIZED COMPUTATIONAL COMPLEXITY\*

ROBERT ENDRE TARJAN†

Abstract. A powerful technique in the complexity analysis of data structures is amortization, or averaging over time. Amortized running time is a realistic but robust complexity measure for which we can obtain surprisingly tight upper and lower bounds on a variety of algorithms. By following the principle of designing algorithms whose amortized complexity is low, we obtain "self-adjusting" data structures that are simple, the sible and efficient. This paper surveys recent work by several researchers on amortized complexity.

"Amortized Computational Complexity", 1985

# What work are you proudest of?

Proudest? It's hard to choose.

I like the self-adjusting search tree data structure that Daniel Sleator and I developed.

#### Self-Adjusting Binary Search Trees

DANIEL DOMINIC SLEATOR AND ROBERT ENDRE TARJAN

AT&T Bell Laboratories, Murray Hill, NJ

Abstract. The splay tree, a self-adjusting form of binary search tree, is developed and analyzed. The binary search tree is a data structure for representing tables and lists so that accessing, inserting, and deleting items is easy. On an n-node splay tree, all the standard search tree operations have an anotice time bound of O(log n) per operation, where by "amortized time" is meant the time per operation averaged over a worst-case sequence of operations. Thus splay trees are as efficient as balanced trees when total running time is the measure of interest. In addition, for sufficiently long access sequences, splay trees are as efficient, to within a constant factor, as static optimum search trees. The efficiency of only tree comes not from an explicit structural constraint, as with balanced trees, but from applying a simple restructuring heuristic, called splaying, whenever the tree is accessed. Extensions of splaying give an applied forms of two other data sucretures lexicographic or multidemissional search trees and link/

"Self-Adjusting Binary Search Trees - Splay Tree", JACM, 1985

#### Splay(x,T):

Moving node x to the **root** of the tree T by  $\cdots$ 

SEARCH
$$(x,T)$$
 RETURN  $x^*/\Lambda$ 

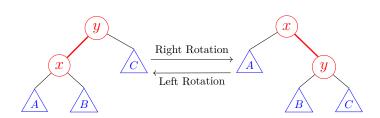

Insert
$$(x,T)$$
 assume  $x \notin T$ 

$$\mathrm{Delete}(x,T)\quad \mathsf{ASSUME}\; x\in T$$

$$T \leftarrow \text{Join}(T_1, T_2) \quad \text{assume } x \in T_1 < y \in T_2$$
 
$$(T_1, T_2) \leftarrow \text{Split}(x, T) \quad \text{return } x \in T_1 \leq i \land y \in T_2 > i$$

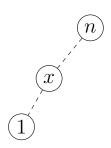

### Splay(x,T):

Moving node x to the **root** of the tree T by performing a sequence of **rotations** along the path from x to the root.

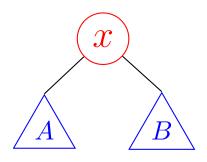

#### A chain of length n

## A sequence of n Splay

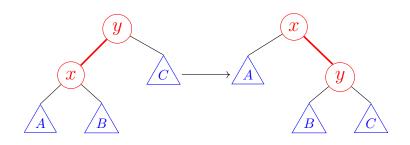

$$\sum_{i=1}^{n} c_i = \Theta(n^2)$$

$$\bar{c}_i = \Theta(n)$$

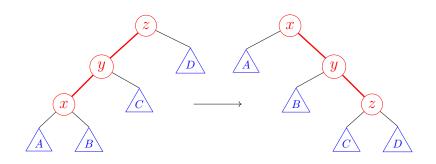

Case 0: x is the root

CASE 1: zig (zag)

$$y = p(x)$$
 is the root

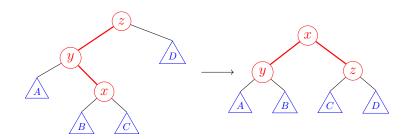

## CASE 2: zig-zig (zag-zag)

$$y = p(x)$$
  $z = p(y)$ 

$$x = lc(y)$$
  $y = lc(z)$ 

$$(1): y-z$$
  $(2): x-y$ 

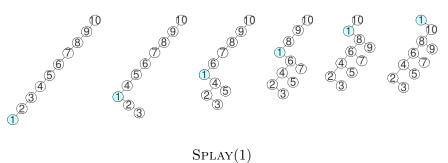

## CASE 3: zig-zag (zag-zig)

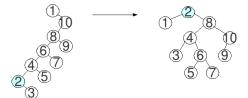

$$y = p(x)$$
  $z = p(y)$ 

$$x = rc(y)$$
  $y = lc(z)$ 

$$(1): x - y$$
  $(2): x - z$ 

```
1: procedure SPLAY(x, T)
        while x \neq T.root do
                                        \triangleright Case 0
2:
            switch · · · do
 3:
                case 1: zig
4:
 5:

$$\Phi_{i-1}$$
  $\overset{ ext{SPLAY}_i}{ ext{the } i ext{-th SPLAY}}$  :

 $\Phi_{i-1} \, \triangleq \, \Phi_{0'} \, \operatorname{ITER}_1 \, \Phi_{1'} \, \cdots \, \underbrace{\Phi_{k-1} \, \operatorname{ITER}_k \, \Phi_k}_{\text{the $k$-th ITERATION}} \cdots \, \operatorname{ITER}_l \, \Phi_l \, \triangleq \, \Phi_i$ 

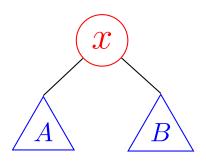

$$egin{aligned} \hat{c}_{ ext{SPLAY}_i} &= \sum_{1 \leq j \leq l} \hat{c}_{ ext{ITER}_j} \ &= \sum_{1 \leq i \leq l} \left( c_{ ext{ITER}_j} + \left( \Phi_{ ext{ITER}_j} - \Phi_{ ext{ITER}_{j-1}} 
ight) 
ight) \end{aligned}$$

$$\hat{c}_{\text{ITER}_j} = c_{\text{ITER}_j} + (\Phi_{\text{ITER}_j} - \Phi_{\text{ITER}_{j-1}})$$

By Case Analysis.

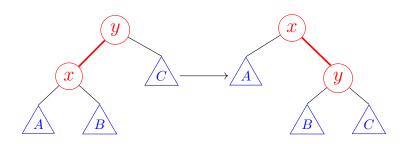

$$\hat{c}_j = c_j + (\Phi_j - \Phi_{j-1})$$

Remember: ITER

Case 0

$$\hat{c}_j = c_j + (\Phi_j - \Phi_{j-1})$$
$$= 0 + 0$$
$$= 0$$

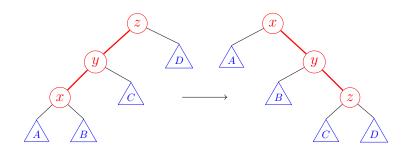

Case 1: zig

$$\hat{c}_j = c_j + (\Phi_j - \Phi_{j-1})$$

$$= 1 + r_j(x) + r_j(y) - r_{j-1}(x) - r_{j-1}(y)$$

$$\leq 1 + r_j(x) - r_{j-1}(x)$$

$$\leq 1 + 3(r_j(x) - r_{j-1}(x))$$

Case 2: zig-zig

$$\begin{aligned} \hat{c}_j &= c_j + (\Phi_j - \Phi_{j-1}) \\ &= 2 + r_j(x) + r_j(y) + r_j(y) - r_{j-1}(x) - r_{j-1}(y) - r_{j-1}(z) \\ &= 2 + r_j(y) + r_j(y) - r_{j-1}(x) - r_{j-1}(y) \\ &\leq 2 + r_j(x) + r_j(z) - 2r_{j-1}(x) \\ &\leq 3(r_j(x) - r_{j-1}(x)) \end{aligned}$$

$$r_{j-1}(x) + r_j(z) = \log s_{j-1}(x) + \log s_i(z)$$

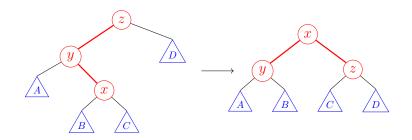

$$\leq 2 \log \left(\frac{s_{j-1}(x) + s_j(z)}{2}\right)$$

$$\leq 2 \log \left(\frac{s_j(x)}{2}\right)$$

$$= 2 \log s_j(x) - 2$$

$$= 2r_j(x) - 2$$

 $r_i(z) \leq 2r_i(x) - r_{i-1}(x) - 2$ 

CASE 3: zig-zag

$$\hat{c}_{j} = c_{j} + (\Phi_{j} - \Phi_{j-1})$$

$$= 2 + r_{j}(x) + r_{j}(y) + r_{j}(y) - r_{j-1}(x) - r_{j-1}(y) - r_{j-1}(z)$$

$$\leq 2 + r_{j}(y) + r_{j}(z) - 2r_{j-1}(x)$$

$$\leq 3(r_{j}(x) - r_{j-1}(x))$$

$$\hat{c}_{\text{ITER}_j} \le \begin{cases} 0, & \text{CASE 0} \\ 1 + 3(r_j(x) - r_{j-1}(x)), & \text{CASE 1} \\ 3(r_j(x) - r_{j-1}(x)), & \text{CASE 2} \\ 3(r_j(x) - r_{j-1}(x)), & \text{CASE 3} \end{cases}$$

$$\begin{split} \hat{c}_{\mathrm{SPLAY}_i} &= \sum_{1 \leq j \leq l} \hat{c}_{\mathrm{ITER}_j} \\ &= \sum_{1 \leq j \leq l} \left( c_{\mathrm{ITER}_j} + \left( \Phi_{\mathrm{ITER}_j} - \Phi_{\mathrm{ITER}_{j-1}} \right) \right) \\ &\leq 3 \big( r_{\mathrm{ITER}_l}(x) - r_{\mathrm{ITER}_0}(x) \big) + 1 \\ &= 3 \big( \log n - r_{\mathrm{ITER}_0}(x) \big) + 1 \\ &\leq 3 \log n + 1 \\ &= O(\log n) \end{split}$$

#### Theorem (BALANCE THEOREM)

$$\sum_{1 \le i \le m} c_{\text{Splay}_i} = O\Big((m+n)\log n\Big)$$

Proof.

$$\begin{split} \sum_{1 \leq i \leq m} c_{\text{SPLAY}_i} &= \left(\sum_{1 \leq i \leq m} \hat{c}_{\text{SPLAY}_i}\right) + \left(\underbrace{\Phi_{\text{SPLAY}_0} - \Phi_{\text{SPLAY}_m}}_{\text{net decrease in potential}}\right) \\ &\leq m \log n + \frac{n \log n}{} \\ &= (m+n) \log n \end{split}$$

$$\Phi = \sum_{x \in T} r(x)$$

## Splay(x)

#### Self-Adjusting Binary Search Trees

DANIEL DOMINIC SLEATOR AND ROBERT ENDRE TARJAN

AT&T Bell Laboratories, Murray Hill, NJ

Abstract. The splay tree, a self-adjusting form of binary search tree, is developed and analyzed. The binary search tree is a data structure for representing tables and lists so that accessing, inserting, and deleting items is easy. On an n-node splay tree, all the standard search tree operations have a monotized time bound of C/log n/) per operation, where by "amortized time" is meant the time per operation averaged over a ownst-case sequence of operations. Thus splay trees are as efficient ablanced trees when total running time is the measure of interest. In addition, for sufficiently long access sequences, splay trees are a selficient, to within a constant factor, a static optimum search trees. The efficiency of splay trees comes not from an explicit structural constraint, as with balanced trees, but from applying a simplified forms of two other data structures: lexicographic or multidimensional search trees and link/ cut trees.
